ABOUT OSDI

OSG-Sterling Die, Inc. was incorporated in 2006. It is made up of the Forming Tool Division of OSG USA and Sterling Die, Inc.

The OSG-USA Forming Tool Division, founded in 1968, was the master distributor of forming tools in the U.S. for OSG Corporation, headquartered in Toyohashi, Japan. OSG has grown to be the world leader in the design and manufacture of forming tools and gages. OSG maintains a high standard of excellence for technology, quality and customer service. OSG is dedicated to making great strides in advancing the technology of the forming tool industry. It's world-class Research and Development facility in Japan employs highly trained engineers that pride themselves in continuously improving tools used in the forming industry. The superior quality of OSG's forming tools has helped gain the support and trust of customers worldwide.

Sterling Die was founded in Cleveland, Ohio in 1948 as a supplier of thread rolling dies to the local Cleveland fastener industry. Since that time, Sterling has grown into the largest producer of thread rolling dies in the United States, servicing not only domestic customers but also customers in over 20 countries. Its dies are routinely used for manufacturing products for automotive, agricultural, construction industries, as well as, other durable goods industries.

OSG-Sterling Die's workforce has many years of experience in designing and manufacturing thread rolling dies, as well as, dies for other forming applications. Its factory is fully equipped with the latest in manufacturing equipment to ensure capability in meeting close tolerances for the most exacting applications. In addition, Sterling has in-house heat-treating capabilities which ensure that metallurgical quality is provided on dies tailored for specific applications.

OSG-Sterling Die maintains a large inventory of standard thread rolling dies, as well as, a large stock of semi-finished die blanks. As a result, it can provide fast delivery on special, made to order dies. In addition, Sterling can provide special stocking programs to fit specific customer's needs.

In house engineering of thread rolling dies is accomplished utilizing computer aided design software specifically developed for Sterling's use. Once dies are designed, the designs are verified in simulation software to ensure that die geometries match intended use and manufacturing capability.

OSG-Sterling Die is an ISO 9001-2008 certified company. Design and manufacture of all products are in compliance with this standard.

ABOUT OSG

OSG has manufacturing factories in 15 countries and provides high quality, high performance products for customers worldwide. OSG has established a quality assurance system to control the quality and consistency of all products manufactured in its global facilities. OSG focuses on providing high quality products, on time and at a reasonable price.

BOLT MAKER • SINGLE FACE DIES

MACHINE SCREW

Boltmaker single face dies have a threaded profile that provides a uniform rate of penetration over approximately two-thirds of the die length. The remaining dwell section accurately sizes the thread. These dies can be used for rolling ASME 1A, 2A and 3A, as well as ISO class 6g and 4h right hand, single lead threads.

Sterling brand, standard boltmaker dies are made from tool steel and are suited for general purpose applications.

Dies can be supplied on a special basis for other machines and face depths, as well as from other materials. In addition, other thread forms, left hand threads and multiple leads can be supplied.

THREAD PITCH	MACHINE	FACE DEPTH	STERLING

UNR, UN, ISO

DUPLEX FACE DIES

Duplex dies have threads on both faces, offering twice the life of single face dies. Four settings may be used with duplex dies when the depth of the face is in excess of two thread lengths. These dies can be used for rolling ASME class 1A, 2A and 3A, as well as ISO class 6g and 4h, right hand single lead threads. The minimum depth of die face should be at least two pitches greater than the length of thread to be rolled. Select the nearest larger depth of die face whenever possible.

Standard Machine Screw dies are offered in three different brands. The Sterling brand, made from tool steel, is suited for general purpose applications. The Hypro brand, made from premium tool steel, provides higher performance when rolling larger production quantities. The OSG brand, also made from premium tool steel, is treated with a special proprietary surface treatment which provides even higher performance when rolling difficult to form materials.

Dies can be supplied on a special basis for other machines and face depths, as well as, from other materials. In addition, other thread forms, left hand threads and multiple leads can be supplied; either as Duplex, Single Face or Split Face style.

TYPE A

GIMLET POINT • SINGLE FACE DIES

Type A gimlet dies point the screwblank and roll the threads simultaneously, eliminating the need for prepointing the blanks prior to rolling threads. In addition, these dies may be used for threading pinch pointed or header pointed blanks. Dies are made for Type A tapping screws with single lead, right handed threads made to American Standard B 18.6.4 specifications.

Standard Type A dies are OSG brand and are offered in two styles-- one with standard die face depth and the Exoform-SS which has full die face depth. The Exoform-SS reduces set-up time by eliminating filler blocks. Both styles are made from premium tool steel and are treated with a proprietary surface treatment which provides high performance when rolling difficult to roll materials.

Dies can be supplied on a special basis for other machines and face depths, as well as, from other materials. In addition, other thread forms, left hand threads and multiple leads can be supplied for standard or for inverted (reverse) roll applications.

TYPE AB

GIMLET POINT • SINGLE FACE DIES

Type AB gimlet dies point the screwblank and roll the threads simultaneously, eliminating the need for prepointing the blanks prior to rolling threads. In addition, these dies may be used for threading pinch pointed or header pointed blanks. Dies are made for Type AB tapping screws with single lead, right handed threads made to American Standard B 18.6.4 specifications.

Standard Type AB dies are offered in three different brands. The Sterling brand, made from tool steel, is suited for general purpose applications. The Hypro brand, made from premium tool steel, is designed for the high performance needed when rolling larger quantities. OSG brand is offered in two styles— one with standard die face depth and the Exoform-SS which has full die face depth. The Exoform-SS reduces set-up time by eliminating filler blocks. Both styles are made from premium tool steel and are treated with a proprietary surface treatment which provides high performance when rolling difficult to roll materials.

Dies can be supplied on a special basis for other machines and face depths, as well as, from other materials. In addition, other thread forms, left hand threads and multiple leads can be supplied for standard or for inverted (reverse) roll applications.

Type B and BP duplex dies have threads on opposite faces and may be used for two settings - one for each face. Thread is single lead, right handed and conforms to American Standard B 18.6.4 specifications. Dies may be used for either flat or round head screws. When using for Type BP, the point must be formed before thread rolling.

Standard B & BP dies are OSG brand. These dies are made of premium tool steel and are treated with a special proprietary surface treatment which provides high performance when rolling difficult to form materials.

Dies can be supplied on a special basis for other machines and face depths, as well as from other materials. In addition, other thread forms, left hand threads and multiple leads can be supplied for standard or for inverted (reverse) roll applications.

TYPE F

SINGLE FACE DIES

Type F single face dies are supplied with full formed taper threads on the point. Threads approximating machine screw threads are single lead, right hand and conform to American Standard B 18.6.4 specifications. The flutes in the tapered end of the thread are rolled simultaneously with the threads.

Standard Type F dies are OSG brand. These dies are made from premium tool steel and are treated with a special proprietary surface treatment which provides high performance when rolling difficult to form materials.

Dies can be supplied on a special basis for other machines and face depths, as well as from other materials. In addition, other thread forms, left hand threads and multiple leads can be supplied for standard or for inverted (reverse) roll applications.

LICENSED PRODUCTS

OSG-Sterling Die is licensed to supply thread rolling dies for many proprietary fastener designs. Our engineers work closely with fastener design engineers to develop products which provide fastening solutions for the automotive, electronic and construction industries. After development, OSG-Sterling Die maintains engineering data to support licensees with their production tooling requirements. OSG-Sterling Die is restricted in supplying dies to only licensed fastener manufacturers.

MATERIALS & TREATMENTS

MATERIAL SELECTION

A2	Tool Steel steel with good toughness characteristics. Normally supplied on dies used for rolling tapping screw threads in general purpose applications.
D2	Tool Steel with good wear resistant properties. Normally supplied on dies used for rolling machine screw threads in general purpose applications.
TS5	Premium Tool Steel with good wear and toughness characteristics. Normally supplied on dies for rolling longer runs and/or for stainless steel fasteners.
M2	High speed steel offers increased die life when rolling selected stainless steel and heat treated fasteners.
M42	Premium high speed steel for rolling fasteners of high tensile strength or hardness. Recommended for aircraft applications.

RELATIVE MATERIAL CHARACTERISTICS

SURFACE TREATMENTS

TREATMENT	INFO	A2	D2	TS5	M2	M42
Gamma Treatment	A proprietary surface treatment which can be used on both tool steel and high speed steel dies to reduce fatigue failure.	√	√	√	√	√
Nitride Treatment	A surface treatment which can be used on high speed steel and premium tool steel dies to increase wear resistance.			√	√	√
SQT Treatment	A proprietary surface treatment which can be used on high speed steel and premium tool steel dies to increase toughness, as well as, wear resistance.			√	√	√

OPTIONS

SPECIAL STARTS

Blank slippage in the thread rolling operation leads to premature die failure and poor quality parts. OSG-Sterling normally supplies dies with a light sandblast; but can offer three special options to minimize slippage:

Sandblast	To minimize slippage, the start end of the dies can be sandblasted with a courser media. Two different starting finishes are offered--regular and course.
Serrations	Sometimes referred to as cross-nicks. These traverse notches are applied to the start ends of the die.
EDM	A rough EDM finish can be applied to the start end of the dies. This surface is rougher than sand blast and is only applied to the die's thread crests.

When ordering a special starts on your dies please indicate whether you are rolling with the top edge, bottom edge (reverse roll) or both edges.

EDGE PREPARATIONS

OSG-Sterling Die normally supplies dies with the top edge that has been beveled and brushed. It can provide a ground chamfer or radius run out on special request.

GROUND CHAMFER

When ordering a special chamfer, please specify the chamfer angle and length.

RADIOUS RUN OUT (RRO)

For RRO please specify the chamfer angle and the RRO length in pitches.

When ordering a special edge preparation on your dies please indicate whether you are rolling with the top edge, bottom edge (reverse roll) or both edges.

LIFT HOLES

OSG-Steling Die normally supplies lift holes to accept a 1/2"-13 eyebolt. Lift holes are tapped 3/4" deep and are provided on sets which exceed 65 pounds in weight. Lift holes are provided on the top of single face dies. On duplex face dies lift holes are tapped on both the top and bottom. Special lift holes can be supplied upon request.

SET UP GUIDE

1. GENERAL

The thread-rolling die cost per thread produced is directly related to number of parts obtained in the useful life of the dies. Each time a pair of dies is used, there is a loss encountered in the life of the dies due directly to variations in setup. Die life and die cost per part depend greatly on the care and attention given to setup of the dies and control of blank diameters and material.

Proper setup of the dies is of prime importance. Failure to make a proper setup accelerates the wear to the thread rolling surfaces of the die caused by fatigue. The presence of abrasive material in the coolant also contributes to premature die failure. Careful attention to the control of operating conditions will greatly extend the useful life of thread rolling dies.

Machines should be maintained in good operating condition. The machine rams should be tight and unnecessary looseness eliminated. Die pockets should be kept in good condition and be free from burrs and chips that could affect the proper seating of the dies. Stationary die blocks must seat firmly on the base and against the adjusting screws.

2. INSERT DIES IN DIE POCKETS

The dies should be placed and clamped in the die pockets with trademarks in the down position. Make sure the die pockets are clean and the dies rest solidly in the die pockets. Dies must not move in the die pockets during the rolling operation. Filler blocks may be used under the dies, when depths of die faces are less than the depths of the die pockets, and must be parallel and free of any burrs.

3. CHECK POSITION OF DIES FOR UNIFORM HEIGHT AND LENGTHWISE PARALLELISM

The dies should be checked with a straight edge, as shown in illustration, to insure dies are setting at the same height. The top edges of the dies must be collinear to the axis of the machine stroke and also parallel with each other. The accurate positioning of the dies eliminates unnecessary adjustment when the dies are later checked for match.

4. POSITION STRAIGHT PORTION OF DIE FACES FOR APPROXIMATE DISTANCE APART

The threaded faces of the dies must also be in a parallel position with each other in order for the dies to finish roll the thread to size during the last few revolutions of the blank. With the dies in parallel position, adjust the spacing of the dies until they are approximately 0.005 to 0.010 apart at the point section at the finish end of the dies. Be sure the rises on the dies do not contact each other.

5. CHECK BLANKS FOR CORRECT DIAMETER, LENGTH AND MATERIAL CONDITIONS

Blank diameters must contain the correct volume of material to form the threads to proper profile and diameter. If the blank contains too much material, the dies become overloaded; and if too little material, the threads will not be completely formed. Blank diameters must therefore be held within prescribed limits of size and tolerances commensurate with the thread specifications for most economical die life. Recommended blank diameters for Types A and AB screws are given on page 19.

Different thread rolling die settings may be required to cover the full diameter limit range produced by new and worn blank header dies. The blank diameter limits for a given setting should not vary more than the permitted blank tolerance, otherwise overloading of the thread rolling dies can result. By keeping different lots of formed blanks segregated into individual blank diameter limit groupings, the thread rolling dies may be readily set up for rolling the individual groupings, with little or no die adjustment for thread size.

It is important that the lengths of the blanks are not less than the finished length of the thread. Blank lengths equal to or in excess of the thread lengths are preferred. Blanks that are too short will produce threaded points with stringers and in some cases, no threaded points at all. Blanks should be checked to make sure they are not bent or out of round since these conditions will tend to make the blanks slip in the dies when rolling and result in premature die failure. If the hardness of the blanks is not uniform, variation in threaded points may occur and result in good points, short or no points, and points with stringers. Hard wire may cause the slugs from the self-pointing operation to break off prematurely with resulting threads having short or broken points. Very soft wire tends to stretch during the self-pointing operation and prevents the slug from separating from the blank, thereby rolling points with stringers. Process annealed wire of Rockwell B60-80 hardness will generally give best results.

6. ADJUST PUSHER FINGER

The pusher finger should be made to contract the diameter of the blank between the head and the start of the tapered threaded point as shown in the illustration. The thickness of the finger should be approximately 0.005 less than the minimum minor diameter of the thread. Make sure there is no interference between the pusher finger and cut off section of the die. The end of the finger contacting the blank must be at a right angle to the top of the die to insure proper introduction of the blank into the dies.

In the blank loading position, the finger should be in the fully retracted position to allow the blank to be inserted between the dies. The finger then moves forward and pushes the blank firmly against the roll-on of the stationary die and the face of the moving die. The finger should hold the blank axis vertically until the moving die rotates the blank forward between both dies. In the forward position, the finger should extend approximately 1/2 the blank diameter beyond the end of the stationary die. Blanks that do not start to roll properly can damage the dies and the machine, and will not be rolled uniformly.

7. POSITION BLANKS VERTICALLY FOR SCREW HEAD CLEARANCE

In order for the threads to be rolled close the underside of the head (or shoulder) on a blank, it is important that the blank be located between the dies with the head close to the top edges of the die.

The manner in which the blank is presented to the dies is controlled by the vertical setting of the automatic feeding mechanism and the top surface of the pusher finger in relation to the top edges of the thread rolling dies.

Interference of the head of the blank with the top edges of the dies may result in reduced die life. Sufficient clearance should be made available between the underside of the blank head and the top edges of the dies so the blank may roll freely over the entire lengths of the dies. The amount of clearance depends on rolling conditions. In some instances, the endwise stretching of the blank will raise the head of the blank away from the dies as the blank is rolled. This may permit the head of the blank to rest on the top edges of the dies at the start of the rolling.

Dirty, oily, coated or poorly formed blanks that cause slippage during the rolling will cause the blanks to pull down into the dies and result in interference between the heads of the blanks and the top edges of the dies.

8. MATCH THE DIE THREADS

The matching of the threads on the moving die with the threads on the stationary die is a very important factor in setup. It is essential when rolling single lead threads, that the dies be positioned so the crests of the threads on long die are exactly opposite the roots of the threads on the short die at a point where the pusher finger introduces the blank to the dies and the blank starts to roll. For double lead threads, the crests of the threads on both dies must be opposite each other.

If the threads on the dies are improperly matched, an inferior product thread will be produced and reduced die life will result. To determine whether or not the threads on the dies are in match, place the blank in a position with the pusher finger holding the blank against the threaded surfaces of the dies at the point where the dies start to roll the blanks. Move the ram forward until the dies have picked up the blank and rotated

the blank 180 degrees. Then mark the blank relative to one of the dies. Reverse the direction of the ram and remove the blank. Examine, under a magnifying glass, the impressions made on the blank by the dies. The impressions produced by one die must be in exact alignment with the impressions produced by the other die, for the threads of the dies to be in match. Sterling dies are prematched but because of machine variations, the impressions of the blank may not always be in alignment. To correct this condition, the moving die has to be repositioned laterally by means of the available adjustments provided on the machine. On machines not having lateral adjustment, the endwise position of the moving die may be changed by either shimming, or grinding off the finished end of the moving die.

9. ADJUST THE DIES FOR CORRECT THREAD DIAMETER

With the die threads properly matched, manually operate the machine and roll a blank through the full length of the dies. Since most spaced thread minor diameters are determined by the thread form on the dies, it is common practice to only check the thread produced for correct major diameter. When making a setup, it is desirable to position the dies apart so the first power rolled sample thread will not be rolled to a full depth of thread. Diameter size is attained by changing the space between the dies through the use of die adjustments built into the machine for this purpose.

Overloading the dies and stalling of the machine may be avoided by gradually adjusting the setting of the dies for desired thread size. Should the major diameter of the threads be oversized, increase the spacing between the dies. Should the major diameter of the thread be undersized, when rolling a fully formed thread with a minimum blank diameter, it will be necessary to increase the blank diameter by an amount that will bring the major diameter within the minimum major diameter limit.

When the application of a spaced thread also requires the checking of minor diameter limits, the adjusting of the dies for correct thread size must take this into consideration.

If a thread is found to have taper outside of the thread diameter limits, it can only be corrected by placing suitable shims in back of either the top or bottom of the rear face and the lower edge as shown by the illustration.

10. MAKE TRIAL RUN

When the die setup is complete, the dies should be clamped firmly in place and the feeding mechanism placed in operation for the trial run. If the threads being rolled are not uniform, make sure the dies are not moving inside the die pockets of the machine. Otherwise check the feeding mechanism, variation of blank size and variation in material hardness. Serrations have been incorporated in the die design to prevent slipping of the blanks between the dies when rolling at machine speeds. Should slipping occur, it may be eliminated by dry blasting the entire threaded faces of both dies with coarse grit. Oily or coated blanks will cause slippage. Slippage will not occur as readily with clean and straight round blanks.

When high-speed machines are running at capacity, minor adjustments in the position of the ram and/or pusher finger may be required.

11. MODIFYING ROLLED THREADED POINTS

Making alterations to the dies may modify the threaded points of the product thread. To reduce length of points threads, stone the serrated surface of the die as shown in upper illustration. To increase the length of the point threads, stone the crests of the upper thread adjacent to the cut off edge as shown in lower illustration.

OBSERVE: STONE MOVING DIE IN MACHINE, (LIGHTLY). IF NECESSARY STONE STATIONARY DIES ALSO

12. COOLANTS

The use of improper coolants can be the cause of blank slippage. Water-soluble coolants are considered most satisfactory.

The points of the product threads may be altered by changing the position of the coolant application on the dies. Shorter points may result when the coolant is applied to the starting ends of the dies, and longer points when applied to the finishing ends of the dies.

TROUBLESHOOTING GUIDE

PROBLEM	POSSIBLE CAUSES
Slivers or flakes	1. Dies not in match
	2. Tipped start
	3. Deep cross-nicking on dies
	4. Slipping at start
	5. Improper helix angle on dies
	6. Machine and dies too large and clumsy for the job
	7. Overfilling dies
	8. Material not adaptable to cold working
	9. Seamy stock
Drunken threads	1. Dies not in match
	2. Tipped start
	3. Crooked relief on dies
	4. Slipping at start
	5. Improper helix angle on dies
	6. Inaccurate dies
OFF SIZE THREADS	
1. PD and OD both oversize	Oversize blanks
2. PD oversize, OD right size	Oversize blanks, if finished thread is full, die thread is too shallow
3. PD oversize, OD undersize	Insufficient squeeze on dies. If finished thread is full, die thread is too shallow
4. PD right size, OD oversize	Blank too large. Die thread deeper than necessary
5. PD right size, OD undersize	Blank too small. If finished thread is full, die thread is too shallow
6. PD undersize, OD oversize	Too much squeeze. Die thread deeper than necessary
7. PD undersize, OD right size	Blank too small. Die thread deeper than necessary
8. PD and OD both undersize	Blank too small
Out of round	1. Out-of-round blank
	2. Too much pressure on finish end of dies
	3. Poor thread form on the relief of the die
	4. Dies too short for the job
	5. If thread is full on one side and not on the other, poor match or crooked start
	6. Material not ductile enough for coldworking
TAPER	
1. PD straight, OD tapered and not filled out on small end	Tapered blank
2. PD and OD both tapered some way	Tapered blank, and dies set up with taper to match
3. PD and OD tapered in opposite directions and thread not filled out an end with small OD	Dies not squeezed tight enough on edge with large PD and small OD

PROBLEM	POSSIBLE CAUSES
Thread with expanded lead	Expanded lead in the dies
Thread with contracted lead	1. Contracted lead in dies
	2. Hard material (Rockwell 18-C scale and harder) will contract slightly when released from rolling dies. For accurate work, use dies with expanded lead.
Poor thread form	1. Poor thread form in the dies
	2. Dies not in match
	3. Crooked start
	4. Machine and dies too large and clumsy for the job
Line running axially down one side	1. Insufficient relief on the stationary die and too much pressure on the finish end
	2. Not gradual enough release of pressure at finish end
	3. Dies too short for the job
Thread filled out in center but not at ends, or vice versa	1. Face of die not flat
	2. Blank with varying diameter from end to end
End threads not filled Out	This can be minimized by chamfering the ends of the blank
Split thread	1. Seamy stock
	2. Too much pressure on dies, usually at finish end
	3. Dies too short for the job
Poor finish on thread	1. Corresponding poor finish on the dies
	2. Dies that are worn out or broken
	3. Dies not in match
	4. Slipping
	5. Deep cross-nicking on start
	6. Material not ductile enough for coldworking
Crests not filled out. Many users do not consider this a serious objection. By allowing their screws to pass with crests not filled out, overloading of dies is avoided and die life is prolonged	1. Blank too small
	2. Die thread too deep
Unfilled gimlet point threads	1. Oversize blanks cause screws to roll out of dies
	2. Undersize blank point
	3. Short straight section of blanks
	4. Blanks improperly positioned
Overfilled gimlet point threads	1. Undersize blanks cause screw to roll down into dies
	2. Oversize blank point
	3. Long straight section of blanks
	4. Blanks improperly positioned

TRIM DIES

With OSG trim dies, tight tolerances can be met while keeping a fine micro finish. We can also meet your special tolerance requests.

For a Hex Trim Die quotation please supply the outside diameter, height, and the across the flat dimensions. For other styles please provide a print. Dies are normally made from M2 material; but other materials can be used upon request. Both CVD and PVD TiCN coatings are available.

BENT & NIB TAPS

SNT - SHORT NUT TAP

A tap that can either be used by connecting to a bent shank or short shank. SNT are stocked as standard items at OSG.

NBT - NIB TAP

This tap is used by directly screwing onto a bent shank with a thread hole. Please supply with a sample tap when requesting a quotation.

BNT - BENT SHANK TAP

This tap is used on automatic tapping machines. The tap will be connected with an SNT and bent shank. Please supply a sample tap when requesting a quotation.

SERIES	
EX-HS	V-SUS
Metric and inch sizes available. These taps are specially designed for tapping cold forged nuts. Taps are manufactured from high speed steel and coated with TiN treatment. Hypro Brand taps are manufactured on CNC manufacturing technology which ensures high quality and consistency in tapping performance.

TiN and TiCN coating increases wear resistance and provides anti-welding properties which increase tap life.

Hypro taps are developed specifically for nut production utilizing high vanadium high speed steel.

RACK DIES

OSG rack dies are made from the highest quality steel (EXO-M®). Our proprietary surface treatment increases surface hardness thereby greatly reducing abrasive wear and chipping.

Below are typical results that show why many high volume shaft producers prefer the OSG, EXO-M, rack dies for their production needs. OSG rack dies are available for rolling splines, threads, grooves and gears. Racks can be used individually or in combination to roll multiple features, such as spline and groove.

PART	DIE SIZE		TYPICAL TOOL LIFE	
	LENGTH (IN)	WIDTH (IN)	D2 RACKS	OSG EXO-M
Alternator Shaft	16	1.185	100,000	250,000
Speedometer Worm	36	1.575	30,000	110,000
Drive Shaft	24	2	20,000	64,000
Drive Shaft	24	4.725	10,000	25,000
Turbine Shaft	24	1.35	70,000	120,000
Turbine Shaft	24	1.37	18,000	35,000

RECONDITIONING PROGRAM

BEFORE

AFTER

OSG-Sterling Die offers a die reconditioning service in their facility in Parma, Ohio. Utilization of this program can lead to significant cost savings over the cost of purchasing new tooling. Flat dies, cylindrical dies and rack dies can be reconditioned.

Flat dies are either reground by removing minimal material on the die thickness or reground to customer's specification. Cylindrical dies are reground to the next suitable diameter for the requested pitch. Rack dies are reconditioned by removing the existing form profile and then regrounding a new profile. After grinding, a shim plate is attached to the rack to bring it into new rack dimensions.

Upon receipt of dies for reconditioning OSG-Sterling performs a full inspection to ensure that the dies are suitable for regrinding. If they are not suitable for regrind, they will be returned to the customer.
